1 Introduction

We all encounter arguments in our lives frequently. When talking to friends, listening to political discussions, or even making decisions in our head. These arguments can get heated and complex since humans have different beliefs and motivations. Finding a common ground or a "correct" conclusion is complicated and sometimes impossible. However, these imperfections are what make us humans. Artificial Intelligence (AI), conversely, needs to act precisely and logically [10]. To do so, the data needs to be stored and structured in a way, that AI can extract informations from it. This is part of knowledge representation and reasoning and that is why much research is being done in that field [9, 23].

Arguments can have many forms [27]. For instance, arguments can be seen as derivations of conclusions, based on assumptions or premises. Such premises can be facts or defeasible assumptions. Relations among arguments are key for driving (automated) argumentative reasoning. A prominent relation between arguments is that of an attack relation, or counter-argument relation. For instance, an argument might attack another. As an example, one argument might conclude that a square is red, while another is concluding that a square is blue. These two arguments are conflicting, and mutually attack each other. Another example would be that an argument is based on a witness statement, while a counter-argument to this one claims that the witness is not truthful, leading to a one-directional attack.

If an argument a is a counterargument of another argument b , we can say that a attacks b . With this abstraction, we can abstract our model with directed graphs. The arguments are represented as nodes, and the attacks as directed edges [12]. Now we can define argumentation frameworks (AFs) and use them to evaluate conclusions [14]. In many cases, viewing arguments as abstract entities is sufficient to carry out argumentative reasoning. Such reasoning is defined via so-called argumentation semantics, which define criteria which (sets of) arguments are deemed jointly acceptable. One of the first pioneers in the topic of argumentation frameworks was Dung. He defined the structure and functionalities in 1995 [11].

Semantics define subsets of arguments that have a certain relation to each other. Dung defined different semantics [11] like conflict-free (cf), admissible (adm) and stable (stb). To be precise, conflict-free and admissible are semantical properties but we will treat them as semantics. According to Dung's definitions, a set S is conflict-free if there are no attacks between the arguments in S . The definition of conflict-freeness is mainly a building block for the other semantics. A stable extension, is a conflict-free set, if every argument, which is not in S , has an attacker which is in S . Finally, an admissible set is a conflict-free set, where each argument in S has a defender in S . A defender in this context means an argument which attacks an attacker of an argument in S .

Since AFs can get very big and complicated, another layer of abstraction can be added. This abstraction layer is called *clustering* and generalizes multiple arguments into one bundled cluster [25]. In this thesis we refer to the clustered AF as *abstract AF* and the original AF, where no clustering occurs is called *concrete AF*. Clustering of arguments is a technique to reduce the number of arguments and to provide a high-level view of a given AF. Here, clustering means that arguments can be clustered together in clusters (or clustered arguments). In general, as is the case with many abstraction techniques, clustering can change conclusions that can be drawn from an abstracted formalism. A clustering is said to be *faithful* if no erroneous conclusions can be drawn that is not part of the original, non-abstracted, structure. Otherwise, if conclusions can be drawn that are not there on the original structure, we say that these are *spurious* conclusions.

In our case, the semantics of conflict-free, admissibility, and stable semantics were "lifted" to the case with clustered arguments. That is, a clustered (abstracted) version of conflict-free sets, admissible sets, and stable extensions was defined on clustered AFs. These semantics respect the clustering of arguments. Then, e.g., an abstract admissible set is spurious if there is no (concrete, non-abstract) admissible set matching this one in the concrete AF. If no such spurious sets exist, then the clustered AF is said to be faithful, w.r.t. the concrete AF.

For instance, let us consider a real-world example like the weather. We can define arguments.

- *a*: The sky is blue.
- *b*: The atmosphere scatters the sunlights and makes the sky appear blue.
- *c*: There exist photographs of a blue sky.
- *d*: Photographs can be fake.
- *e*: At sunrise the sky appears to be orange.
- *f*: Observations can alter, depending on the time.

With this knowledge basis, we can create a concrete AF $G = (A, R)$. Where we abstract the arguments into nodes and transform the opposing statement into attacks as shown in Figure 1.1a. An opposing statement in this context would be for instance the argument *a* (i.e. *The sky is blue*) and *e* (i.e. *At sunrise the sky appears to be orange*). Since both statements can not be true at the same time, they are contradicting, or in other words, attacking each other. If we apply another layer of abstraction, we obtain, e.g. the abstract AF $\hat{G} = (\hat{A}, \hat{R})$ defined in Figure 1.1b. We call arguments which are clustered, *clustered arguments* and arguments which are not in clusters *singletons*. Here, we created a single cluster consisting of the arguments $\{a, b, c, e, f\}$.

Now we can compute the sets of the according semantics (cf, adm, stb). The definitions of the semantics are defined in the Chapter 2. To reduce cluttering, we keep this example to the stable semantics. The stable extensions of the AF G are $\mathbf{stb} = \{\{d, e\}, \{b, d, f\}\}$.

Figure 1.1: Concrete and abstract AF

By computing the stable extensions of the abstract AF $\hat{G} \text{ stb} = \{\{d\}, \{d, \hat{g}\}\}$, we can observe that the AF is spurious due to the extension $\{d\}$, since the abstract stable extension cannot be mapped to one of the concrete stable extensions.

When concretizing (i.e. removing an argument from the cluster) the argument c , we create a new AF $\hat{G}' = (\hat{A}', \hat{R}')$ depicted in Figure 1.2, which has the following stable extensions $\text{stb} = \{\hat{g}, d\}$. This extension can be mapped to both stable extensions of the concrete AF G , by mutating the cluster \hat{g} with $\{e\}$ or $\{b, f\}$. Thus, we created a faithful abstract AF.

Figure 1.2: Concretized AF \hat{G}'

When producing an AF with multiple layer of abstractions, we obtain a high-level view of the concrete AF. This simplification has the drawback to lose some details. To still have a deep understanding of the structure to some extend, extracting single arguments of the cluster by concretizing them can be helpful. This also allows the user to have a direct impact to the outcome and produce customized faithful AFs.

Creating abstract, faithful AFs can be challenging and is the main focus of this thesis. Unfortunately, drawing a conclusion from an AF can be challenging, e.g., it can be NP-complete and sometimes even be beyond NP to decide whether an argument is acceptable under a specific argumentation semantics [13]. In fact, the complexity of proving faithfulness or spuriousness of an AF is \prod_2^P hard [25]. In practice, this means, that to obtain a result, multiple instances or calls of a SAT-Solver need to be invoked.

We created one of the first tools to produce an abstract AFs based on a concrete AFs. We cover different setups and usages, including different semantics and base functionalities. The main contributions of this thesis are as follows.

- We provide algorithms for computing abstract semantics of a given clustered AF. That is, our algorithms are capable of computing or enumerating all extensions under abstract conflict-free, admissible, and stable semantics.
- Based on our algorithms for computing abstract semantics, we provide algorithmic solutions for checking faithfulness of a given clustered AF. We develop two

approaches in this regard: (i) one of based on breadth-first-search (BFS) and (ii) one based on depth-first search (DFS). While the algorithm based on BFS first calculates all original extensions and abstract extensions of a given AF and clustered AF, respectively, the DFS variant iteratively computes abstract extensions of the clustered AF and verifies (non-)spuriousness of this extension.

- Towards user-interaction, for a given AF and clustered AF, we provide an algorithm for concretization, by which we mean that a user can select arguments inside clusters to be made concrete (singletons). We then refine the clustered AF until faithfulness is reached, since the extraction of the user-defined arguments may result in spurious reasoning.
- We implemented our algorithms in TODO how? and provide the implementations in open-source.
- In an experimental evaluation, ... TODO results.
- ...

We provide an open source implementation of the previously listed tools [6].

2 Background

In this chapter we discuss the background of the thesis. We start with the basic definition of argumentation frameworks (AFs) in Section 2.1. Next we treat the clustering of AFs in Section 2.2 and finally we provide a quick overview of SAT-Solvers in Section 2.3.

TODO: update when adding sections

2.1 Argumentation Frameworks

Argumentation frameworks were first formally described by Dung in 1995 [12]. They represent an information state, where various conclusions can be drawn from. An AF $G = (A, R)$ consists of two parameters: a set of arguments A , and a collection of relations R , called attacks which describe the conflicts between the arguments.

They are mostly used in the fields of Artificial Intelligence (AI), e.g. in automated reasoning and logic programming [16, 26]. But do also find their applications in other fields like natural language processing [4], trust and reputation systems [19], legal and medical reasoning [2], and even in game theory and strategic reasoning [22].

AFs are represented by directed graph, where the nodes are an abstraction of the arguments A , and the arrows represent the attacks R . Let us define an AF $G = (A, R)$ with the arguments $A = \{a, b, c, d, e\}$ and the attacks $R = \{(a, b), (b, b), (a, c), (c, a), (c, d), (d, e), (e, d)\}$.

This AF can be represented as a directed graph as shown in Figure 2.1.

Figure 2.1: AF G

To be able to conclude something, out of an abstract AF, we need to define semantics. Semantics define a subset of argument sets that satisfy the semantic-specific rules. Dung already defined different semantics [11] like conflict-free, admissible and stable.

Conflict-Free According to Dung’s definitions, a set is conflict-free if there are no attacks between the arguments in the conflict-free set. A conflict-free set is mainly a building block for the other semantics, which means here that each admissible set or stable extension is conflict-free.

Definition 1 ([11]). *Let $G = (A, R)$ be an AF. Then a set $S \subseteq A$ is conflict-free in G if and only if for each $a, b \in S$ we have $(a, b) \notin R$.*

Example 1. *The conflict-free sets of the concrete AF G in Figure 2.1 are $\{\}, \{a\}, \{c\}, \{d\}, \{e\}, \{a, d\}, \{a, e\}, \{c, e\}$.*

Admissible A set is admissible, if each argument in the admissible set has a defender in the admissible set.

Definition 2 ([11]). *Let $G = (A, R)$ be an AF. Then a set $S \subseteq A$ is admissible in G , if and only if $S \in cf(G)$ and if $a \in S$ with $(b, a) \in R$, then there is a $c \in S$ with $(c, b) \in R$.*

Example 2. *The admissible sets of the concrete AF G in Figure 2.1 are $\{\}, \{a\}, \{c\}, \{e\}, \{a, d\}, \{a, e\}, \{c, e\}$.*

Stable An extension is stable, if it is conflict-free, and if for every argument, which is not in the stable extension, there exists an attacker in the stable extension.

Definition 3 ([11]). *Let $G = (A, R)$ be an AF. Then a set $S \subseteq A$ is stable in G . If and only if $S \in cf(G)$, $b \notin S$ implies that there is an $a \in S$ with $(a, b) \in R$, and if S does not attack an $a \in S$ then $b \notin S$ whenever $(a, b) \in R$.*

Example 3. *The stable extensions of the concrete AF G in Figure 2.1 are $\{a, d\}, \{a, e\}$.*

The specific semantics rules can also be defined via a Boolean formula. Which then can be used to encode the AFs to be solvable with different solvers like Answer Set Programming (ASP) [5] or, as in our case, with a Boolean Satisfiability Solver (SAT-Solver) [1]. Unfortunately, drawing a conclusion from an AF can be challenging, e.g., it can be NP-complete and sometimes even be ”beyond“ NP to decide whether an argument is acceptable (whether an argument can be defended successfully against attacks within the AF) under a specific argumentation semantics [13].

2.2 Clustering of Argumentation Frameworks

When talking about AFs in general, we already have an abstraction layer. By clustering, we add another layer of abstraction where we combine different arguments into one or multiple so called *clusters*. The arguments which are not clustered are called *singletons*. The name is derived from set theory, where singleton refers to a set containing exactly one argument. By definition, a cluster is a single entity (composed of multiple arguments) which can be integrated in an AF to reduce the complexity. While reducing the overall complexity of the AF with clusters, we add a new computation layer: computing *faithful*

clustered AFs. The term *faithful* describes the property of a clustered AF, that every abstract semantics extension can be mapped to a concrete semantics extension. If the clustered AF creates a semantics set which cannot be mapped to a concrete set, we call it *spurious*.

Clustered abstract AFs can also be modelled with graphs. One can represent each singleton argument as a node, attacks as arrows, and each cluster can be represented by a rectangle with every clustered argument inside of it. Let us have a look at an example and define AF $\hat{G} = (\hat{A}, \hat{R})$ with the arguments $\hat{A} = \{d, e, \hat{h}\}$, where the cluster \hat{h} contains the arguments $\{a, b, c, d\}$ and the attacks being $\hat{R} = \{(\hat{h}, d), (d, e), (e, d), (\hat{h}, \hat{h})\}$. This AF can be represented as a directed graph as shown in Figure 2.2.

Figure 2.2: AF \hat{G} clustered

Since clusters can not be treated the exact same way as an argument, we need to refine the semantics definitions. When referring to the alternative semantics used in clustered AFs, we call them *abstract* semantics (e.g. abstractly conflict-free (\hat{cf}), abstractly admissible (\hat{adm}) and abstractly stable (\hat{stb})). Let us consider a clustered AF $\hat{G} = \{\hat{A}, \hat{R}\}$ and redefine the semantics.

Conflict-Free A set of arguments is abstractly conflict-free, if there is no attack between the singletons of the set.

Definition 4 ([25]). *Let $\hat{G} = (\hat{A}, \hat{R})$ be an AF. Then a set $S \subseteq \hat{A}$ is conflict-free in \hat{G} if and only if for each $\hat{a}, \hat{b} \in \text{singleton}(S)$ we have $(\hat{a}, \hat{b}) \notin \hat{R}$.*

Example 4. *The abstractly conflict-free sets of the abstract AF G in Figure 2.2 are $\{\}$, $\{d\}$, $\{e\}$, $\{\hat{h}\}$, $\{e, \hat{h}\}$, $\{d, \hat{h}\}$.*

Admissible A set of arguments is abstractly admissible, if it is abstractly conflict-free and if every singleton which is being attacked, has a defender.

Definition 5 ([25]). *Let $\hat{G} = (\hat{A}, \hat{R})$ be an AF. Then a set $S \subseteq \hat{A}$ is admissible in \hat{G} if and only if $S \in \hat{cf}(\hat{G})$ and if $\hat{a} \in S$ with $(\hat{b}, \hat{a}) \in \hat{R}$ with $\text{singleton}(\hat{a})$, then there is a $\hat{c} \in \hat{G}$ with $(\hat{c}, \hat{b}) \in \hat{R}$.*

Example 5. *The abstractly admissible sets of the abstract AF G in Figure 2.2 are $\{\}$, $\{e\}$, $\{\hat{h}\}$, $\{e, \hat{h}\}$, $\{d, \hat{h}\}$.*

Stable A set of arguments is abstractly stable, if it is abstractly conflict-free and if an argument is not in the abstractly stable extension, it implies that an argument in the abstractly stable extension is attacking it. Furthermore if the abstractly stable extension is not attacking an argument, then every singleton attacking the argument is not in the abstractly stable extension.

Definition 6 ([25]). Let $\hat{G} = (\hat{A}, \hat{R})$ be an AF. Then an extension $S \subseteq \hat{A}$ is stable in \hat{G} if and only if $S \in \hat{cf}(\hat{G})$, $\hat{b} \notin S$ implies that there is an $\hat{a} \in \hat{S}$ with $(\hat{a}, \hat{b}) \in \hat{R}$, and if S does not attack an $\hat{a} \in S$ then $\hat{b} \notin S$ whenever $(\hat{a}, \hat{b}) \in \hat{R}$ and singleton (\hat{b}) .

Example 6. The abstractly stable extensions of the abstract AF G in Figure 2.2 are $\{e, \hat{h}\}, \{d, \hat{h}\}$.

Let us have a look at a concrete example to explain faithfulness. The concrete AF $G = (A, R)$ has the following arguments $A = \{a, b, c, d, e\}$ with these attacks: $R = \{(a, b), (b, b), (a, c), (c, a), (c, d), (d, e), (e, d)\}$. This AF can be represented as a directed graph shown in Figure 2.3a.

Now we can group the arguments $\{a, b, c, d\}$ together into one single cluster \hat{h} . The arguments for the abstract AF $\hat{G} = (\hat{A}, \hat{R})$ would then be $\hat{A} = \{e, \hat{h}\}$, where the cluster \hat{h} is composed of $\{a, b, c, d\}$ and the according attacks are $\hat{R} = \{(\hat{h}, e), (e, \hat{h}), (\hat{h}, \hat{h})\}$. The attacks are directly derived from the concrete AF. If an argument is clustered, the cluster inherits the attacks from the argument. The emerging AF can be represented as a directed graph shown in Figure 2.3b.

Figure 2.3: Concrete and abstract AF

If we compare the stable extensions of the concrete AF G (e.g. $\mathbf{stb} = \{\{a, e\}, \{a, d\}\}$) with the abstractly stable extensions of the abstract clustered AF \hat{G} (e.g. $\mathbf{s\hat{t}b} = \{\{\hat{h}\}, \{e\}, \{e, \hat{h}\}\}$), we see that it is spurious due to the abstractly stable extension $\{e\}$ which cannot be mapped to one of the concrete stable extensions. The mapping of semantics extensions with clustered AFs is done the same way as for concrete AFs, except that clusters can mutate to every possible combination of the clustered Arguments. In our example, the cluster \hat{h} can mutate to $\{a\}, \{b\}, \{c\}, \{d\}, \{a, b\}, \{a, c\}, \{a, d\}, \{b, c\}, \{b, d\}, \{c, d\}, \{a, b, c\}, \{a, b, d\}, \{a, c, d\}, \{b, c, d\}, \{a, b, c, d\}$. To create a faithful clustered AF, we can concretize one or more arguments of the cluster. By concretizing the argument $\{d\}$, we obtain a new AF $\hat{G}' = (\hat{A}', \hat{R}')$ with the arguments $\hat{A}' = \{d, e, \hat{h}\}$, where the cluster \hat{h} is composed of $\{a, b, c\}$, and the according attacks are $\hat{R}' = \{(d, \hat{h}), (d, e), (e, d), (\hat{h}, \hat{h})\}$.

With this definition we can build the concretized abstract graph \hat{G}' in Figure 2.4.

Every abstractly stable extension in Figure 2.4 (e.g. $\{d, \hat{h}\}, \{e, \hat{h}\}$) can be mapped to one of the concrete stable extensions of G , which means that the clustered AF \hat{G}' is faithful.

Figure 2.4: Concretized AF \hat{G}'

2.3 Boolean Satisfiability

A SAT(isfability)-Solver is used to compute Boolean formulas in a rather efficient way [3]. The main purpose is to determine, if a formula is satisfiable (e.g. the variables of the formula can be set to *true* or *false* s.t. the expression evaluates to *true*). If no combination of setting the variables to *true* or *false* s.t. the formula evaluates to *true* is found, we call the Boolean expression UNSAT(isfiable). Most of the SAT-Solvers do also provide a model, if a Boolean expression is satisfiable.

SAT-Solvers do find there applications in various domains, e.g. in verification and validation of software and hardware [15, 24]. But also in AI and machine learning [17] and even in security [7, 18].

The decision problem of deciding whether a Boolean formula is satisfiable (SAT) is NP-complete, and it was the first problem to be shown to be NP-complete [8]. Subsequently, many other problems were shown to be NP-hard, due to a reduction from SAT.

Each year further optimizations of SAT-solvers are developed. There are several competitions which are being ran in different classes [20]. Meanwhile, SAT-Solvers are so specialized, that there is no overall best SAT-Solver, but it is dependent on the application field. An overall good performing and easy to implement SAT-Solver, which we also used in this thesis is the z3 SAT-Solver [21].

3 Algorithm to obtain Faithful Clustering

In this chapter we have a closer look at the algorithms we designed and how they work. We begin with Section 3.1, where we define the Boolean encodings for the semantics. In Section 3.2 we explain, the concretization of a clustered argument. Next, in Section 3.3 we explain how the concretizer list (a list of clustered arguments which are mutated to singletons) is computed. The approach to compute faithful clustered AFs is then described in Section 3.4. And finally we state the heuristics and refinements in Section 3.5.

TODO: Update when adding sections

3.1 Encodings

We previously defined the semantics in mathematical notation. But since we use SAT-Solving to compute extensions under a chosen semantics we develop in this section encodings in Boolean logic of the semantics of clustered AFs. We develop these encodings for (abstract) conflict-free, (abstract) admissible, and (abstract) stable extensions. For each semantics we present the corresponding Boolean encoding and an example.

In general, given an AF $\hat{G} = (\hat{A}, \hat{R})$, we will use Boolean variables corresponding to arguments. That is, if $a \in \hat{A}$ is an argument, then a is also a Boolean variable. The intended meaning is then that in a truth-value assignment a variable a is *true*, then there is a corresponding set of arguments with a in the set. Formally, if τ is a truth-value assignment on the variables in \hat{A} , then the corresponding set of arguments is defined as $\{a \in A \mid \tau(a) = 1\}$.

Conflict-Free We begin with (abstract) conflict-free sets. Recall that a set of (clustered) arguments is conflict-free if there is no attack between singletons in the set. Thus, the empty set is always part of the conflict-free sets.

Definition 7. Let $\hat{G} = (\hat{A}, \hat{R})$ be an abstract AF. Where \hat{A} are the representations of the arguments as Boolean variables and \hat{R} are the attacks between the arguments.

$$\hat{cf}(\hat{G}) = \bigwedge_{a \in A_{SINGLE}} \left(\bigwedge_{b: (b,a) \in R, b \in A_{SINGLE}} \neg(a \wedge b) \right)$$

Example 7. Let us have a look at an example and define the abstract AF $\hat{G} = (\hat{A}, \hat{R})$ to be the AF depicted in Figure 3.1. With the arguments $\hat{A} = \{a, b, c, d\}$ and the attacks $\hat{R} = \{(a, a), (a, b), (b, c), (d, a), (d, b), (d, c)\}$.

Figure 3.1: Abstract AF \hat{G}

By applying the formula from Definition 7 to the AF \hat{G} , we obtain the following Boolean expression.

$$\psi = \neg(b \wedge a) \wedge \neg(b \wedge d) \wedge \neg(a \wedge d) \wedge \neg(a \wedge a) \wedge \\ \neg(c \wedge b) \wedge \neg(c \wedge d)$$

The models of ψ in this example are $\{\{\}, \{b\}, \{c\}, \{d\}, \{\hat{h}\}, \{b, \hat{h}\}, \{c, \hat{h}\}, \{d, \hat{h}\}\}$.

If we compare the models of ψ with the conflict-free sets of \hat{G} , we can observe that they are equal. In fact, Definition 7 is a Boolean representation to obtain conflict-free sets from an AF. The formula can be applied to concrete and abstract AFs, because if no cluster is present, the formula corresponds to the previously defined conflict-free formula and only adds the layer of abstraction if atleast one cluster is present.

Admissible Next we continue with (abstract) admissible sets. Recall that a set of arguments is abstractly admissible, if it is abstractly conflict-free and if every singleton which is being attacked, has a defender. For admissibility, the empty set does always satisfy the criteria and therefore is part of the admissible sets.

Definition 8. Let $\hat{G} = (\hat{A}, \hat{R})$ be an abstract AF. Here the arguments as Boolean variables denote to \hat{A} and the attacks of G denote to \hat{R} .

$$adm(\hat{G}) = cf(\hat{G}) \wedge \bigwedge_{a \in A_{SINGLE}} (a \rightarrow \bigwedge_{b: (b,a) \in R} (\bigvee_{c: (c,b) \in R} c))$$

Example 8. Let us have a look at an example and define the AF $\hat{G} = (\hat{A}, \hat{R})$ to be the AF depicted in Figure 3.2. Where the arguments are $\hat{A} = \{a, b, c, d, e\}$ and the attacks $\hat{R} = \{(a, a), (a, b), (b, c), (d, a), (d, b), (d, d), (d, e), (e, d)\}$.

Figure 3.2: Abstract AF \hat{G}

By applying the formula defined in Definition 8 to the AF \hat{G} , we obtain the following Boolean expression.

$$\begin{aligned}\psi = & (\neg(a \wedge a) \wedge \neg(a \wedge d) \wedge \neg(b \wedge d) \wedge \neg(b \wedge c) \wedge \neg(b \wedge d) \wedge \neg(c \wedge b) \wedge \neg(d \wedge e) \\ & \wedge \neg(d \wedge d) \wedge \neg(e \wedge d)) \\ & \wedge (a \rightarrow ((a \vee d) \wedge (e \vee d)) \wedge (b \rightarrow ((a \vee d) \wedge (b) \wedge (e \vee d)))) \\ & \wedge (c \rightarrow ((a \vee c \vee d) \wedge (\hat{h}))) \wedge (d \rightarrow (d) \wedge (e \vee d)) \wedge (e \rightarrow (e \vee d))\end{aligned}$$

The models of ψ in this example are $\{\{\}, \{c\}, \{e\}, \{\hat{h}\}, \{c, e\}, \{c, \hat{h}\}, \{e, \hat{h}\}, \{c, e, \hat{h}\}\}$.

If we compare the models of ψ with the admissible sets of \hat{G} , we can observe that they are equal. Indeed, Definition 8 provides a Boolean representation that allows the derivation of admissible sets from an AF. If the AF \hat{G} has no cluster, the formula reduces itself to the previously defined admissible formula.

Stable Finally we take a look at the (abstract) stable extensions. Recall, that a set of arguments is abstractly stable, if it is abstractly conflict-free and if an argument is not in the abstractly stable extension, it implies that an argument in the abstractly stable extension is attacking it. Furthermore if the abstractly stable extension is not attacking an argument, then every singleton attacking the argument is not in the abstractly stable extension. Other than conflict-free and admissible, the empty set is not part of the stable extension.

Definition 9. Let $\hat{G} = (\hat{A}, \hat{R})$ be an abstract AF. In this case, \hat{A} represents the arguments as Boolean variables, and \hat{R} represents the attacks of \hat{G} .

$$stb(\hat{G}) = \hat{c}f(\hat{G}) \wedge \bigwedge_{a \in \hat{A}} (a \vee \bigvee_{b: (b,a) \in \hat{R}} b) \wedge \bigwedge_{a \in \hat{A}} ((a \wedge \bigwedge_{b: (b,a) \in \hat{R}} \neg b) \rightarrow (\bigwedge_{c: (a,c), c \in A_{SINGLE}} \neg c))$$

Example 9. Let us have a look at an example and define the AF $\hat{G} = (\hat{A}, \hat{R})$ to be the AF depicted in Figure 3.3. Where the arguments are $\hat{A} = \{a, b, c, d\}$ and the attacks $\hat{R} = \{(a, a), (a, b), (a, d), (b, a), (b, d), (c, b), (d, a)\}$.

Figure 3.3: Abstract AF \hat{G}

If we apply the encoded formula defined in Definition 9 to the AF \hat{G} , we obtain the following Boolean expression.

$$\begin{aligned} \psi = & ((\neg(a \wedge a)) \wedge (\neg(a \wedge b)) \wedge (\neg(b \wedge a)) \wedge (\neg(b \wedge c)) \wedge (\neg(d \wedge b))) \\ & \wedge ((a \vee a \vee b \vee d) \wedge (b \vee a \vee c) \wedge (d \vee b) \wedge (\hat{h} \vee c)) \\ & \wedge (((a \wedge \neg a \wedge \neg b \wedge \neg d) \rightarrow (\neg a \wedge \neg b)) \\ & \wedge ((b \wedge \neg a \wedge \neg c) \rightarrow (\neg a \wedge \neg d)) \wedge ((d \wedge \neg b) \rightarrow \neg a)) \end{aligned}$$

The models of ψ in this example are $\{\{c, d\}, \{c, d, \hat{h}\}\}$.

By comparing the models of ψ with the stable sets of \hat{G} , we find that they are identical. Specifically, Definition 9 is a Boolean expression to derive admissible sets from an AF. If the AF has no clusters, the Boolean expression reduces to the admissible formula defined earlier.

3.2 Concretizing Singletons

When operating on clustered AFs, a crucial mutation is to extract clustered arguments from a cluster and transform it to a singleton. This is called concretizing. When clustering singletons, the cluster inherits the attacks of the argument, concretizing is the inverse operation. This means, that it needs to revert the changes done by the clustering. Concretizing a list of arguments is done iteratively by duplicating the abstract AF \hat{F} to create a new AF \hat{F}' and transforming it. The transformation is guided by five steps considering the unchanged abstract AF \hat{F} and the concrete AF F . To improve the understanding of each step, we accompany the explanation with the example depicted in Figure 3.4, where we concretize the arguments a and b .

Figure 3.4: Concrete and abstract AF

Step 1: Each argument needing concretization is first removed from the parent cluster and added as a singleton in \hat{F}' . If an argument is not part of a cluster, we ignore it. We do not consider attacks in this step since they depend on the concrete- and abstract AFs. The resulting AF is depicted in Figure 3.5 and the pseudo-code in Algorithm 1.

Figure 3.5: Concretized AF \hat{F}' after Step 1

Algorithm 1 Concretizing Singletons Pseudocode Step 1

Require: $A : AF(a_1, r_1)$ ▷ Abstract Clustered AF
Require: $e : list(Arguments)$ ▷ Concretizer List
1: $N \leftarrow A$ ▷ $N =$ Concretized Cluster
2: **for** a_i in e **do**
3: **for** c_i in $A.clusters$ **do**
4: **if** a_i in c_i **then**
5: $c_i.remove(a_i)$
6: **end if**
7: **end for**
8: $N.addSingleton(a_i)$
9: **end for**

Step 2: We add the new attacks from all concretized arguments to the remaining clusters and vice versa. We must do this after removing the arguments from the clusters because if an argument a attacks argument b in the concrete AF F , and b is part of the cluster \hat{g} in the abstract AF \hat{F} , by concretizing b , the attack (a, \hat{g}) would not be present anymore. The resulting AF \hat{F}' is depicted in Figure 3.6 and the pseudo-code in Algorithm 2

Figure 3.6: Concretized AF \hat{F}' after Step 2

Algorithm 2 Concretizing Singletons Pseudocode Step 2

Require: $C : AF(a_2, r_2)$ \triangleright Concrete AF**Require:** $e : list(Arguments)$ \triangleright Concretizer List**Require:** $N : AF(a_3, r_3)$ \triangleright Concretized Cluster

```
1: for  $e_i$  in  $e$  do
2:   for  $att_i$  in  $C[e_i].attacks$  do
3:     if  $att_i$  to cluster  $c_i$  then
4:        $N.addAttack((e_i, c_i))$ 
5:     end if
6:   end for
7:   for  $def_i$  in  $C[e_i].defends$  do
8:     if  $def_i$  from cluster  $c_i$  then
9:        $N.addAttack((c_i, e_i))$ 
10:    end if
11:  end for
12: end for
```

Step 3: After adding the new attacks, we need to check which attacks from \hat{F} are still present in \hat{F}' . If an attack does not persist through the concretization, we remove it in \hat{F}' . An attack is not present anymore; if we remove one of the arguments being attacked or attacked by argument a from a cluster \hat{f} and no other attack exists, s.t. a is attacked from/attacking an argument within \hat{f} . Selfattacks of clusters could also change by the concretization of arguments. Therefore, we need to check the clusters from which the arguments are concretized. The resulting AF is depicted in Figure 3.7 and the pseudo-code in Algorithm 3.

Figure 3.7: Concretized AF \hat{F}' after Step 3

Algorithm 3 Concretizing Singletons Pseudocode Step 3

Require: $A : AF(a_1, r_1)$ ▷ Abstract Clustered AF
Require: $C : AF(a_2, r_2)$ ▷ Concrete AF
Require: $N : AF(a_3, r_3)$ ▷ Concretized Cluster

```
1: for  $r_i$  in  $A_{r_1}$  do
2:   if  $r_i.defender$  is cluster and  $r_i.attacker$  is cluster then
3:     if  $!(r_i.attacker$  attacks any of  $C[r_i].defender)$  then
4:        $N.removeAttack(r_i)$ 
5:       continue
6:     end if
7:   end if
8:   if  $r_i.defender$  is cluster then
9:     if  $!(r_i.attacker$  attacks any of  $C[r_i].defender)$  then
10:       $N.removeAttack(r_i)$ 
11:      continue
12:    end if
13:  end if
14:  if  $r_i.attacker$  is cluster then
15:    if  $!(r_i.defender$  defends against any  $C[r_i].attacker)$  then
16:       $N.removeAttack(r_i)$ 
17:      continue
18:    end if
19:  end if
20: end for
```

Step 4: In this step we add the new attacks between the singletons. Due to the fact, that we copied all the attacks from \hat{F} , we only have to take into consideration the attacks from or to the concretized singletons. So instead of iterating over all singletons of the AF \hat{F}' , we can limit the attack creation to the concretized singletons. The resulting AF is depicted in Figure 3.8 and the pseudo-code in Algorithm 4.

Figure 3.8: Concretized AF \hat{F}' after Step 4

Algorithm 4 Concretizing Singletons Pseudocode Step 4

Require: $A : AF(a_1, r_1)$ ▷ Abstract Clustered AF
Require: $C : AF(a_2, r_2)$ ▷ Concrete AF
Require: $e : list(Arguments)$ ▷ Concretizer List
Require: $N : AF(a_3, r_3)$ ▷ Concretized Cluster

```
1: for  $e_i$  in  $e$  do
2:   for  $a_i$  in  $C[e_i].attacks$  do
3:     if  $a_i$  is singleton and  $(e_i, a_i)$  not in  $r_2$  then
4:        $N.addAttack((e_i, a_i))$ 
5:     end if
6:   end for
7:   for  $a_i$  in  $C[e_i].defends$  do
8:     if  $a_i$  is singleton and  $(a_i, e_i)$  not in  $r_2$  then
9:        $N.addAttack((a_i, e_i))$ 
10:    end if
11:  end for
12: end for
```

Step 5: The last step is to clean up the argumentation framework \hat{F}' by removing all empty clusters and mutating the clusters with exactly one singleton to the mentioned singleton. The resulting AF \hat{F}' is depicted in Figure 3.9 and the pseudo-code in Algorithm 5.

Figure 3.9: Concretized AF \hat{F}' after Step 5

Algorithm 5 Concretizing Singletons Pseudocode Step 5

Require: $A : AF(a_1, r_1)$ ▷ Abstract Clustered AF
Require: $C : AF(a_2, r_2)$ ▷ Concrete AF
Require: $e : list(Arguments)$ ▷ Concretizer List
Require: $N : AF(a_3, r_3)$ ▷ Concretized Cluster

```
1: for  $c_i$  in  $N.clusters$  do
2:   if  $c_i.argAmount == 1$  then
3:      $c_i \leftarrow Singleton$ 
4:   else if  $c_i.argAmount == 0$  then
5:      $N.remove(c_i)$ 
6:   end if
7: end for
```

3.3 Computation of Concretizer List

When talking about clustering AFs, faithfulness is an important property. If an AF is spurious, we found atleast one semantics extension, which cannot be mapped to a concrete extension. Based on the spurious extensions, we try to mutate the clustered AF, to obtain faithfulness. This mutation is realized through the concretizer list.

The concretizer list is a list of sets of clustered arguments. Each set is a unique combination of arguments, which are being concretized to find a faithful AF. All the sets of the concretizer list are attempted iteratively, where the order is dependend on the size of the set. We use a heuristical approach, putting the main focus on local changes. Here we operate directly on the arguments and its attackers which make a set spurious, instead of applying global changes to the AF. Further, a minimal deviation of the abstract AF is usually desired, so small concretizer sets are checked first.

The input to the computation of the concretizer list is a set of the arguments of all the spurious semantics extensions. The size and computation intensity of the concretizer list is highly dependent on the amount of attacks, each argument of the input set and its neighbours with depth 2 have. This is also the critical part of the faithful AF computation and makes some AFs infeasible to solve.

Let us have a look at an example to demonstrate how the concretizer list is computed. The concrete AF G is defined in Figure 3.10a and the according abstract AF \hat{G} in Figure 3.10b.

Figure 3.10: Concrete and abstract AF

If we have a look at the stable extensions of the concrete AF G , e.g. $\text{stb} = \{\{b, c\}\}$ and at the abstractly stable extensions of the abstract AF \hat{G} , e.g. $\text{stb} = \{\{b, \hat{h}\}, \{\hat{h}\}, \{b\}\}$, we can see that the abstractly stable extensions $\{\hat{h}\}$ and $\{b\}$ are spurious. The input to the concretizer list computation is a collection of the arguments of all the spurious sets, which in this case is $\{b, \hat{h}\}$.

The first step is to filter out the clusters of the input, since clusters are not present in the concrete AF and therefore do not attack any singletons and are not being attacked. So we reduce the concretizer list from $\{b, \hat{h}\}$ to $\{b\}$. The pseudo-code is listed in Algorithm 6.

Algorithm 6 Computation of Concretizer list Algorithm: Prefiltering

Require: $\hat{G} : AF(a_2, r_2)$

▷ Abstract AF

Require: $s : list(Arguments)$

▷ spurious arguments

```

1: for  $s_i$  in  $s$  do
2:   if  $s_i$  in  $\hat{G}$  is cluster then
3:      $s.remove(s_i)$ 
4:   end if
5: end for

```

Next, we have a look at the neighbouring arguments of the current concretizer list. Neighbours in this context are arguments which attack, or are being attacked by an argument. The depth defines how many arguments are between the attacks. A depth of 0 is the actual argument, a depth of 1 represents the direct attacker of the argument and the direct arguments, which are being attacked by the argument. A depth 2 argument is an argument, which has some attack relation (e.g. attacks the argument or is attacked by the argument) with a depth 1 argument.

We used a search depth of 2 in our implementation. So when having a look at our example, we take the defender of depth 1 and 2, in Figure 3.11 depicted in yellow and the attacker with the same depth, depicted in blue. The pseudo-code of this procedure is listed in Algorithm 7. Some arguments can have multiple depths (e.g. argument c . It is a direct attacker of the argument b with depth 0, but also a direct attacker of the argument c with depth 1), than the lower depth is chosen as the representative.

Figure 3.11: Singletons depth with b as viewpoint

Now the concretizer list is expanded with all the possible combinations of the neighbours. The neighbours of the current example are $\{a, c, d, e\}$. When building the combinations, we create the table defined in Table 3.1.

size 1	size 2	size 3	size 4
$\{a\}$	$\{a, c\}$	$\{a, c, d\}$	$\{a, c, d, e\}$
$\{c\}$	$\{a, d\}$	$\{a, c, e\}$	
$\{d\}$	$\{a, e\}$	$\{a, d, e\}$	
$\{e\}$	$\{c, d\}$	$\{c, d, e\}$	
	$\{c, e\}$		
	$\{d, e\}$		

Table 3.1: Combinations of $\{a, c, d, e\}$

Algorithm 7 Computation of Concretizer list Algorithm: Neighbours

Require: $G : AF(a_1, r_1)$ ▷ Concrete AF
Require: $s : list(Arguments)$ ▷ Working List
1: $N \leftarrow []$ ▷ N = list of neighbours
2: **for** s_i in s **do** ▷ Get neighbours
3: **for** $n(1)_i$ neighbour of s_i **do** ▷ depth 1 attacker
4: **for** $n(2)_i$ neighbour of $n(1)_i$ **do** ▷ depth 2 attacker
5: $N.append(n(1)_i)$
6: $N.append(n(2)_i)$
7: **end for**
8: **end for**
9: **end for**

The combination table grows exponentially to the base of 2. Therefore, the size of the neighbours is crucial. If we have too many neighbours, the computation would need too much memory and turns infeasible to compute.

If the user has provided arguments which have to be concretized as program argument, we add them to each combination set. After adding them, we filter for duplicates to keep the concretizer list size to a minimum.

Next, we need to filter out the arguments, which are not in clusters, since singletons are already concrete. This filtering could lead to some duplicates again, which we need to remove once again to minimize the memory consumption and reduce the amount of faithful checks.

Finally, we sort the list by the set size and return it. In the current example we would return the whole table, because no concretizer arguments were provided by the user. So the concretizer list would be $\{\{a\} \{b\} \{c\} \{d\} \{a, c\} \{a, d\} \{a, e\} \{c, d\} \{c, e\} \{d, e\} \{a, c, d\} \{a, c, e\} \{a, d, e\} \{c, d, e\} \{a, c, d, e\}\}$. The pseudo-code for the last step is stated in Algorithm 8.

When concretizing the list, we find a set which leads to a faithful AF: $\{a, c, d\}$ depicted in Figure 3.12.

Figure 3.12: Faithful AF \hat{G}'

Algorithm 8 Computation of Concretizer list Algorithm: Combinations and Cleanup

Require: $G : AF(a_1, r_1)$ ▷ Concrete AF
Require: $\hat{G} : AF(a_2, r_2)$ ▷ Abstract AF
Require: $s : list(Arguments)$ ▷ Working List
Require: $ca : list(Arguments)$ ▷ Concretize arguments parameter
1: $C \leftarrow$ combinations of N with $range(1, len(N) - 1)$ ▷ Combination List
2: **for** ca_i in ca **do** ▷ Parameter Arguments to be concretized
3: **for** c_i in C **do**
4: $c_i.append(ca_i)$
5: **end for**
6: **end for**
7: $C.deduplicate()$
8: **for** s_i in C **do** ▷ Remove clusters
9: **for** a_i in s_i **do**
10: **if** $\hat{G}[a_i]$ is cluster **then**
11: $s_i.remove(a_i)$
12: **end if**
13: **end for**
14: **end for**
15: **return** $s.sortBySize()$

3.4 Algorithmic Approach to Compute Faithful Clusterings

When clustering AFs, information gets lost. If crucial information is abstracted in a way, s.t. we can draw erroneous conclusions, we have a spurious AF. Spurious abstract AFs do not represent the according concrete AFs. Thus, we need to mutate the clustered AF, that only correct solutions can be drawn, which we then call faithful.

3.5 Heuristics and Refinements

TODO: Define every Heuristic and refinement we used for each semantic

TODO: Explain AF creation algorithms (Random + Grid-Based)

4.2 BFS and DFS Approach

TODO: BFS and DFS approach in current research + when BFS is better than DFS

4.3 Generating Semantic Sets

TODO: Semantic sets generation algorithm

4.4 Faithful/Spurious Determination

TODO: Determine faithful/spurious algorithm

4.5 Refuted Theories

TODO: State refuted theories like subsets of spurious also spurious.

REUSE THIS SOMEWHERE:

We encoded the semantics rules into Boolean formula and used the SAT-Solver to evaluate them. To cover all possibilities of AFs, we generalized the formulas and used short notation to concatenate the variables. Let us have a look at a concrete example with an abstract clustered AF $\hat{\mathbf{G}} = (\hat{\mathbf{A}}, \hat{\mathbf{R}})$ defined in Figure 4.1.

Figure 4.1: Abstract AF $\hat{\mathbf{G}}$

For-OR To concatenate all the singletons of the AF \hat{G} , we can use the following notation:

$$\bigvee_{a \in \hat{G}_{SINGLE}} a = c \vee d \vee e$$

For-AND To concatenate all the singletons of the AF \hat{G} , we can use the following notation:

$$\bigwedge_{a \in \hat{G}_{SINGLE}} a = c \wedge d \wedge e$$

For-Attacks To iterate over the attacks \hat{R} we can extract it from the AF as tuple and address the attacker a and defender b :

$$\bigwedge_{(a,b) \in \hat{R}, a \in \hat{G}_{SINGLE}} (a \vee b) = (c \vee c) \wedge (c \vee d) \wedge (c \vee e) \wedge (e \vee d) \wedge (d \vee e)$$
